## Abstract

Electronic health records (EHRs) have emerged among health information technology as “meaningful use” to improve the quality and efficiency of healthcare, and health disparities in population health. In other instances, they have also shown lack of interoperability, functionality and many medical errors. With proper implementation and training, are electronic health records a viable source in managing population health? The primary objective of this systematic review is to assess the relationship of electronic health records’ use on population health through the identification and analysis of facilitators and barriers to its adoption for this purpose. Authors searched Cumulative Index of Nursing and Allied Health Literature (CINAHL) and MEDLINE (PubMed), 10/02/2012–10/02/2017, core clinical/academic journals, MEDLINE full text, English only, human species and evaluated the articles that were germane to our research objective. Each article was analyzed by multiple reviewers. Group members recognized common facilitators and barriers associated with EHRs effect on population health. A final list of articles was selected by the group after three consensus meetings ( $n = 55$ ). Among a total of 26 factors identified, 63% (147/232) of those were facilitators and 37% (85/232) barriers. About 70% of the facilitators consisted of *productivity/efficiency* in EHRs occurring 33 times, increased *quality* and *data management* each occurring 19 times, *surveillance* occurring 17 times, and *preventative care* occurring 15 times. About 70% of the barriers consisted of *missing data* occurring 24 times, *no standards* (interoperability) occurring 13 times, *productivity loss* occurring 12 times, and *technology too complex* occurring 10 times. The analysis identified more facilitators than barriers to the use of the EHR to support public health. Wider adoption of the EHR and more comprehensive standards for interoperability will only enhance the ability for the EHR to support this important area of surveillance and disease prevention. This review identifies more facilitators than barriers to using the EHR to support public health, which implies a certain level of usability and acceptance to use the EHR in this manner. The public-health industry should combine their efforts with the interoperability projects to make the EHR both fully adopted and fully interoperable. This will greatly increase the availability, accuracy, and comprehensiveness of data across the country, which will enhance benchmarking and disease surveillance/prevention capabilities.

**Keywords** Electronic health records (EHR) · Outcomes · Population health · Public health

## Introduction

### Background

Healthcare Information Technology (HIT) is changing how the healthcare industry operates and has already began to reduce waste and help improve health outcomes [1]. A major

This article is part of the Topical Collection on *Transactional Processing Systems*

component of HIT is the Electronic Health Record (EHR). We used the definition of the EHR from the Center of Medicaid and Medicare Services (CMS): Electronic health records are digital forms of patient records that include patient information such as personal contact information, patient’s medical history, allergies, test results, and treatment plan [2]. Some benefits of EHRs include improving efficiency, increasing positive patient outcomes, and population health.<sup>1</sup> Potential improvements in population health include EHRs ability to organize and analyze a large amount of patient information. This is particularly pertinent since the Public Health Data Standards Consortium (PHDSC) and the Center for Disease Control (CDC) completed its project to standardize public

health case reports in accordance with HL7 [3]. This project in 2012 is one example of many ongoing efforts to establish data standards in support of the public health and the EHR.

Population health is “the health outcomes of a group of individuals, including the distribution of such outcomes within a group” [4], and EHRs provide access to public health data to survey the population for potential health improvements or act as a safety net for potential health threats.<sup>5</sup> A new program called “DiSTRIBuTE” that uses the EHRs in the surveillance of population health issues [5], and recent use found that electronic health records were better able to track “weekly influenza trends on an ongoing basis better than and in a “more timely than manual reporting from sentinel providers” [5]. Distributed Surveillance Taskforce for Realtime Influenza Burden Tracking and Evaluation (DiSTRIBuTE), run by the International Society for Disease Surveillance (ISDS), collects aggregated data by age group to improve decision making on public safety, cost, quality, and outcomes. This distributed-data is collected, analyzed, and interpreted in real time. Privacy of information is managed by the Fair Information Practice Principles (FIPPs), and the de-identified data is shared electronically to address specific population-health-related questions. The CDC in 2009 to support the tracking of the H1N1 pandemic, among other examples. EHRs can provide additional screening of health records beyond surveillance that can lead to additional research [5]. Public health surveillance observes a population and brings attention to various health threats or monitors the general health of the population [6]. There is even a positive correlation between the use of EHRs by primary care providers and the ability to accurately report to public health officials [7].

Utilizing and incorporating Electronic Health Records in surveillance and care interventions can help aid the health of the population it serves. Many of these studies have shown significant positive effects of EHRs interaction with public health. Previous research shows how EHRs are being used to surveil various populations, and some review other countries’ use of EHRs for surveillance [8]. Some positive effects that were observed included better surveillance of infectious diseases, improved management of patients with chronic diseases, and identify populations with higher risk factors [8]. The recent shifts in healthcare policy such as The ACA have recommended health practices to focus on preventive care to improve the overall health of the population [1]. Shih and De Leon discovered that physicians who implemented EHRs were better able to deliver recommended preventive care into their practices for low-income populations [9]. Electronic health records have been implemented to provide more coordinated and patient-centered care. EHR implementation in the ICU significantly reduces the central line associated bloodstream infections and surgical intensive care unit mortality rates [10]. EHRs provide secure access to patient information resulting in positive outcomes in relations to quality of care

and productivity [11]. EHR systems have been used to manage chronic disease like diabetes, and it has been found that regular use of the EHR can reduce fragmentation of data and increase continuity of care between providers if the providers participate in health information exchanges [12]. EHRs in the emergency department (ED) improve medical decision making when using a decision tree; It increases the patient’s quality of life, and it was found to be cost-effective [13]. Another cost benefit assessment for using electronic health records for data showed promising results [14]. The European Electronic Health Records for Clinical Research (EHR4CR) has developed an innovative platform that is capable of transforming traditional research processes appeared to be highly beneficial by reducing the actual person-time, operational costs, or average cycle time for Phase II–III clinical trials when compared to current practices in a pre-launch environment [14].

Other studies have illuminated possible barriers to the success of EHRs. Some of these barriers include lack of interoperability, errors in medical information, and the financial resources that are required to accommodate HIT. Medical errors may still occur despite the increase of information being gathered from patients with the use of EHR [15]. Patients who received medical and surgical care showed same outcomes in six diverse states independent of the use of EHRs. No specific benefits in patient outcomes were related to EHRs [16]. Patient satisfaction can be adversely affected by the EHR due to a decrease in attention that a physician exhibits while making notes in the system [17]. Adoption of the EHRs is not without obstacles; however, results of the research is mixed on whether a proper implementation of an EHR could improve the operations of population health.

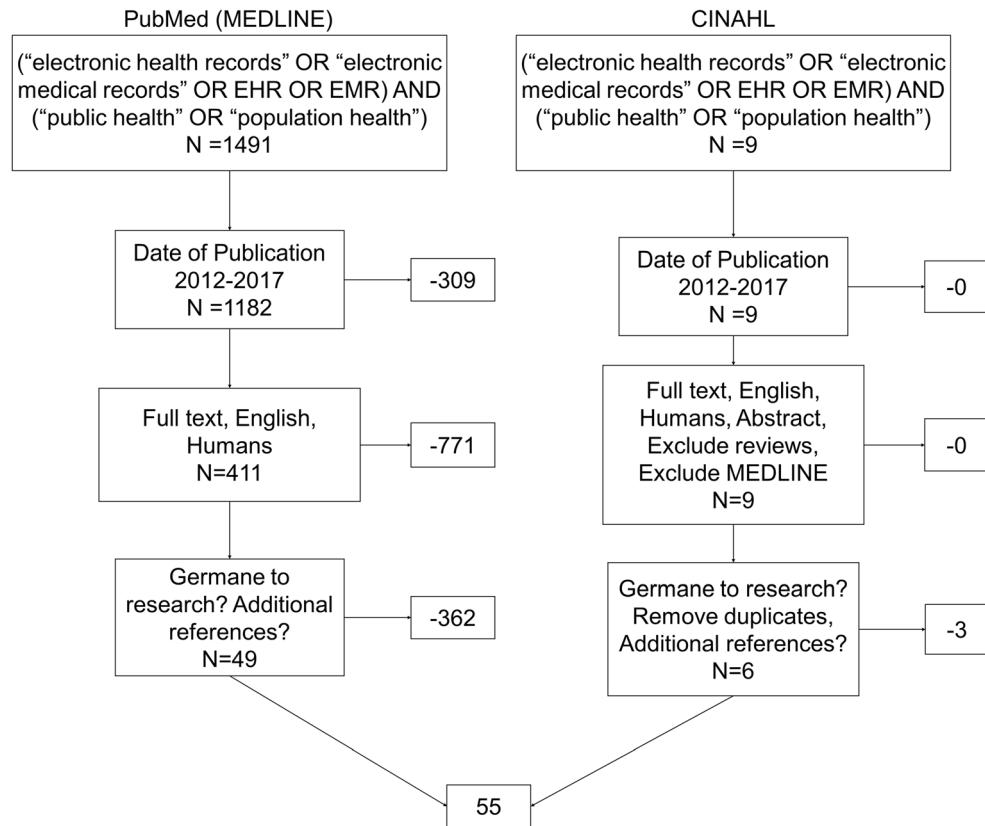

## Objectives

The purpose of this study is to review the literature previously published on the effects of EHRs on population health. Health Information Technology is becoming more widely utilized, however, the industry has still not been able to achieve its overall accessibility. It is our goal to answer whether the use of electronic health information can play a vital role in improving the health of populations, as well as identify key inhibitors to its adoption and/or key use.

## Methods

The articles used for this systematic review were gathered and compiled using PubMed (MEDLINE complete) and The Cumulative Index to Nursing and Allied Health Literature (CINAHL). The search process is illustrated in Fig. 1. The United States National Library of Medicine’s Medical Subject Headings (MeSH) was used to find the key terms related to our topic in PubMed. With the help of MeSH, we

**Fig. 1** Literature Search with inclusion and exclusion criteria

were able to identify the appropriate sub-headings under the key terms. Our final key terms in the search process for both databases were “EHR” “electronic health record” “EMR” “electronic medical record” and “population health” or “public health”. While these terms have distinct definitions from each other, they are often used synonymously. We included both so that the search would be more exhaustive. In accordance with good research practice, we also included Boolean operators and quotation marks in the search string. The initial search in PubMed and CINAHL resulted in 1491 and nine items, respectively. We chose a timeframe of five years to keep the grouping small enough for reasonable analysis. After filtering relevant time frame academic journals, English only, and other peer review selection processes, we were left with 420 articles. Our process was to divide up these 420 abstracts between reviewers in a way that ensured each abstract was read by at least 2 reviewers. We independently assessed the relevance of each abstract in an Excel workbook and then combined the assessments during a consensus meeting. During this meeting we resolved any conflict in the assessments (germane or not germane to our research) to reach a final grouping of 55 articles for full analysis. A Kappa statistic of .83 was calculated, which demonstrates strong agreement among the reviewers, as well as consistency in reading and initial analysis of suitability. The same process was repeated for analysis of the articles that was used for analysis of the

abstracts. Independent observations were recorded and later combined for a consensus meeting. During this second round, reviewers were also asked to pay attention to the references of each article to identify salient resources that may not have been caught by our search. This search did not result in any additional articles added to the group analyzed ( $n = 55$ ).

During the second consensus meeting, reviewers shared their observations of facilitators and barriers to adoption of the EHR for managing public health. Through this process, reviewers categorized and grouped their observations in logical manner. An additional read of the articles took place to identify bias and limitations. These were shared in a third and final consensus meeting.

## Results

The results of our analysis are listed in Table 1. This table includes the source article, the facilitators, barriers, bias, and limitations of the articles analyzed.

We examined the work of 414 authors and co-authors who published 55 works that discuss Electronic Health Records, Population and or Public Health. We identified a total of 232 factors, which consisted of 63% (147/232) facilitators and 37% (85/232) barriers. Utilizing EHRs resulted in a greater number of benefits than negative impacts to population health.

**Table 1** Summary of articles analyzed

Author	Facilitator / enabler for adoption	Themes	Barrier to adoption	Themes	Bias or limitation
Bailey, et al. [18]	- Increased utilization of prevention / primary care - Disease prevention - Utilization can be captured through EHR, even during dramatic upturns - Improved data quality - Improved workflow - Disease surveillance - Improved timeliness - Interoperability	Preventative Care Preventative Care Data Management	- None identified  - Limited sample from Oregon which means the results are not generalizable	None identified	- Limited sample from Oregon which means the results are not generalizable
Houser, et al. [19]	- Surveillance across all registries and all states - Advancing epidemiologic research - Quality reporting	Surveillance Data Management Quality	- Lack of funding  - Lack of medical staff support  - Changing data standards  - Lack of full-time commitments	Cost Limited staff support No standards Critical thinking/treatment decisions No standards Missing data	- Limited sample from Alabama conference - Response bias  - Lack of resources
Metroka, et al. [20]	- Clinical decision support - Improved efficiency - Ease of use - Data sharing - Improved quality - Ease of data collection - Ability to measure intensity of care - Surveillance - Disease prevention	Decision support Productivity/ Efficiency Ease of use Data Management Quality Data Management Productivity/ Efficiency Surveillance Preventative Care	- Lack of standardized data exchange - Records may be missing data - Data contains errors - Data Management - Productivity/ Efficiency - Missing data - Human error in measurement	Missing data / data error Missing data / data error Missing data / data error Missing data / data error	- Limited external validity: This study was restricted to immunizations - Limited external validity: Data only collected at one institution. - Measurement error can be mitigated with training. - Interrater reliability between systems needs to be measured and controlled. - EHR samples are convenience samples which may not be representative of the population.
Blecker, et al. [21]				Cost	- Small sample leads to low statistical power which reduces the external validity.
Flood, et al. [22]				Technology complex	- External validity limited: Study conducted in the correctional setting.
Martelle, et al. [23]	- Improved accessibility - Improved quality of care	Productivity/ Efficiency Quality	- Few incentives  - Few inmates have email which reduces the demand for a patient portal.	None identified	- Selection bias - Gender bias - External validity limited because the gender/race demographics of the sample are not representative of the U.S.
Chambers, et al. [24]	- Financial assistance - Interoperability - Improvement to quality - Surveillance - Access to primary care information provides tailored quality improvement initiatives	Financial Assistance Interoperability Quality Surveillance Productivity/ Efficiency			

**Table 1** (continued)

Author	Facilitator / enabler for adoption	Themes	Barrier to adoption	Themes	Themes	Bias or limitation
Moody-Thomas, et al. [25]	- Improved primary care - Intervention effective in lowering the prevalence of tobacco  - Disease prevention	Quality Health Outcomes	- No independent method for determining the quality of data	No standards	- Quasi-experimental - Patient-reported behavior on bad behavior can be tempered to avoid uncomfortable discussions. - No similar group exists for comparison of results.	
Vogel, et al. [26]	- Sustainability and generalizability - Health outcomes - Data management - Productivity	Preventative Care  Surveillance Quality Health Outcomes Data Management Productivity/ Efficiency	- Human error - Data is typically missing or incomplete - Data error	Human error Missing data / data error Missing data / data error	- The voluntary nature of the Massachusetts League of Community Health Centers can create a fluid status of participating offices, which can also create orphaned data for queries. - Not all primary-care entities cooperate and share with public health entities.	
Calmam, et al. [7]	- Improve surveillance and management of chronic disease - Efficiency	Surveillance Productivity/ Efficiency Interoperability Decision support Preventative care None identified	- Cost - No central agency mandating cooperation of public health with primary care entities.	Cost No standards	- Productivity loss Missing data / data error Technology complex	
Duan, et al. [27]	- Interoperability - Decisions about treatment - Disease prevention - None identified		- Electronic system failures - Inaccurate data (data errors) - Complexity - None identified	None identified	- Information bias caused by misclassification of errors.	
Kawamoto, et al. [28]	- Disease prevention - Improved productivity	Preventative care Productivity/ efficiency		None identified	- Quasi experimental - Control group comparison data were created using a model.	
Behrens, et al. [29]	- Improved efficiency - Surveillance	Productivity/ efficiency Surveillance	- None identified	None identified	- Binning, as is common in Monte Carlo simulations, can cause bias in data. - Machine logic was used for best fit.	
Cross, et al. [30]	- Support care coordination - Increased productivity - Data management	Communication Productivity efficiency Data management	- Interoperability - Cost - Total adoption is a barrier because some physicians don't want to adopt unless referrals will have the technology.	No standards Cost Resistance to change	- Sample restricted to the state of Michigan.	
Tanner, et al. [31]	- Technology is up to date - Patient safety for medications	Current technology Quality	- EHRs can often obscure relevant information. - Fear of unintended consequences from EHRs.	Missing data / data error	- Selection bias: Only pre-meaningful use era adopters were queried. - Does not address causation	
Emani, et al. [32]	- Interoperability - Improved productivity - Decrease medical errors	Interoperability Productivity/ efficiency Quality	- Resistance to change	Resistance to change	- Study was limited to two academic medical centers in one region.	
	- Physician satisfaction	Satisfaction

During the review process, various aspects of electronic health records showed that the utilization of these HIT improves population and public health. Benefits of using electronic medical records describe how EHRs improved the productivity and efficiency of health organizations to better serve populations. Increased healthcare access to individuals provides more comprehensive documentation from the population from the surveillance of public health screening and preventative care. Electronic health records allow health professionals to share and incorporate more public health information among various providers. This improves the population's ability to survey the populations for chronic disease, contagious infections, and allows for more rapid and uniform transference of patient information [7, 18–71]. The incorporation of new technology is expected to have some flaws associated with its integration into the healthcare field [7, 18–71]. Some of the major setbacks of EHRs and EMRs include a temporary decrease in productivity, while staff and medial personal incorporate and train employees to use an entirely new system. Alongside with new operational systems medical efforts, lack of functionality, system failures, and simple resistance to change by providers can occur. These can have negative impacts on public health as missing or incorrect information can be transmitted for surveillance. Other barriers include the inability to generalize one healthcare organization's experience to others due to various types of EHRs and systems to the wide variety of populations and settings. Some healthcare populations have been found to be more accepting of EHRs while others have found it more difficult to incorporate them into a daily routine [1]. The authors were able to organize and examine these themes in the discussion section.

## Additional analysis

Affinity matrices were created to further analyze facilitators and barriers. These matrices are illustrated in Table 2.

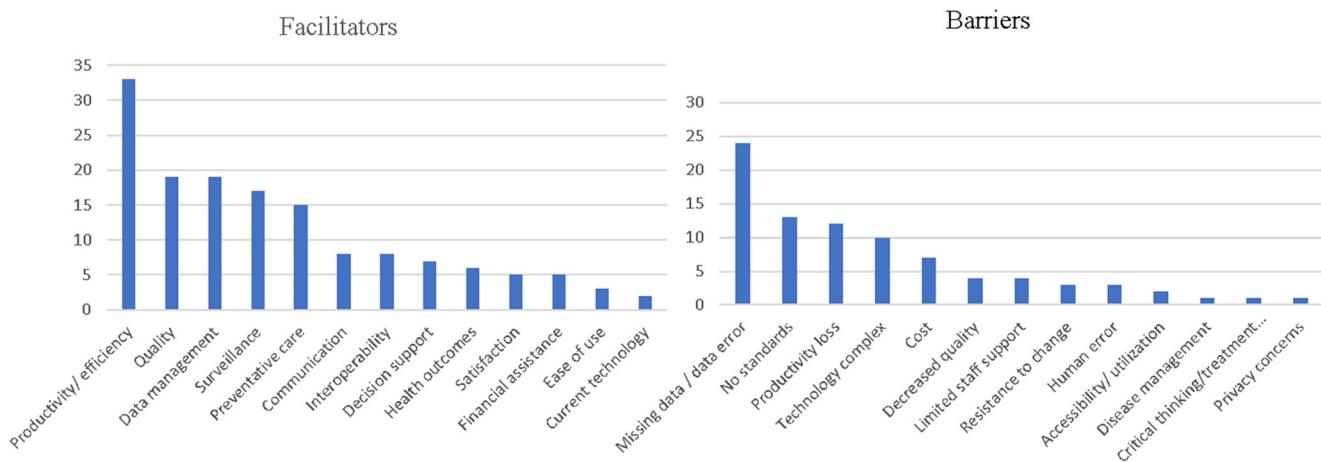

A visual representation of these factors can also be seen in fig. 2.

Thirteen facilitators and 13 barriers were identified. The occurrences of facilitators outweighed those of the barriers 3:2. Several facilitators and barriers were similar and were combined, for instance productivity and efficiency. Articles that mentioned both facilitators are marked in the tables with an asterisk. Facilitators identified are *productivity/efficiency* [19, 21, 22, 24, 25, 27, 28, 30\*, 32, 33–36\*, 38, 43, 45–47\*, 51, 53–56, 59\*, 60, 63, 64, 70, 72, 73], *quality* [19\*, 20, 22, 24–27, 33, 34, 45, 46, 49, 53, 54, 56, 62, 69, 72], *data management* [7, 18–21, 26, 30, 33, 37–39, 41, 48, 54, 64–66, 68, 71], *surveillance* [19, 20, 23, 25, 26, 28, 31, 41, 54, 55, 62, 63, 66, 67, 69\*, 70], *preventative care* [19\*, 23, 26, 28, 30, 36, 37, 39, 52, 62, 63, 65, 68, 69], *communication* [30, 36, 47, 50, 58, 62, 64, 70], *interoperability* [7, 19, 23, 31, 41, 43, 47, 49], *decision support* [7, 19, 34, 56–58, 61], *health outcomes* [25, 26, 44, 53, 58, 61], *satisfaction* [32, 33, 34, 45, 59, 73], *financial assistance* [24, 49, 50, 60, 69], *ease of use* [21, 53, 65], *current technology* [2, 147], *satisfaction* [29, 42, 44, 48, 57, 61].

**Fig. 2** Charts of the frequency of facilitators and barriers

43, 57, 70], financial assistance [23, 47, 48, 58, 66], ease of use [20, 51, 63], and current technology [30, 47]. Barriers identified are missing data / data error [21–23\*, 27\*, 29, 32, 33, 36, 39, 41\*, 46, 48, 50, 51, 55–57, 61, 65, 67, 70], no standards (of data or interoperability) [20\*, 26, 28, 32, 40, 41, 46, 53, 56\*, 63, 68], productivity loss [29, 35, 38\*, 44, 47, 48, 51, 55, 73\*], technology (too) complex [23, 27, 41, 46, 47, 50, 52, 61, 70, 71], cost [7, 19, 23, 29, 58, 61, 62], decreased quality (of data or care) [45, 54, 57, 59], limited staff support [19, 34, 36, 62], resistance to change [30, 32, 36], human error [26, 60, 70], accessibility/utilization [47, 60], disease management [59], critical thinking/treatment decisions [19], privacy concerns [49]. The top five facilitators and top four barriers make up about 70% of the factors observed.

## Discussion

### Summary of evidence

In this systematic review the authors reviewed 55 articles. The analysis identified 13 facilitators and 13 barriers, and facilitators outweighed barriers 3:2. The top three facilitators were an increase in *productivity/efficiency* (greater capacity, more efficient procedures and processes, etc.), an increase in the *quality* of data or care (data that was more accurate, more precise, and contained less error; care that produced higher quality outcomes as a result of more accurate data), and various aspects of *data management* (users were able to access patient data in a more efficient manner). The top three barriers were *missing data* (some data was missing or was not filled in) / *data error* (incorrect data was entered), *no standards* for interoperability (data could not easily be shared between providers), and a *loss of productivity* (teaching users how to use the EHR and data-entry requirements were time consuming and took users away from other duties in the office, which made the office less productive). The results of this review show more positive

than negative factors for the use of the EHR to manage public health and surveillance.

The facilitator most often found in the literature is the increase of either productivity, efficiency, or both. Organizations were maximized time with patients instead of writing documentation. These articles said that EHRs improved the workflow in organizations. Other organizations identified a loss in productivity for the same reason. This could have been due to the stage of implementation in which the organizations were.

With the ability to access a greater number of records in a more productive way, it was not surprising that surveillance accounted for the third most recorded facilitator. Surveillance can utilize information from EHRs to make population and public health predictions as well as track occurrences of infectious diseases and other public health functions to have a better overall review of a population's health.

### Limitations

To control for selection bias, reviewers agreed on definitions and concepts prior to the search and analysis of articles. Each article was reviewed and analyzed by multiple reviewers. A series of consensus meetings was held to share observations and agree on next steps. The team calculated a *Kappa* statistic of 0.83 which in fact shows a high level of agreement.

Publication bias is likely to occur because publishers tend to publish articles with significant relationships, and therefore articles that did not result in significant findings were not able to be selected for this review [72]. Our search was limited to PubMed and CINAHL, which may have impacted the scope of our results. These databases were chosen for their comprehensive scope and positive reputation in research.

### Comparison to other research

Contrary to studies on the adoption of the EHR, the authors found that cost was not as prevalent a barrier in using EHRs in

support of public health. This could be a result of sufficient time passing for financial incentives to alleviate the concern. The articles reviewed intimated that EHRs were cost effective, enhance productivity/efficiency and quality, and they are conducive for data collection when missing data is analyzed. Standards for interoperability need to continue to progress: Until all EHR solutions reach the same level of interoperability, data sharing cannot be assured.

## Conclusion

Additional research should follow from this review. Productivity was both a facilitator and a barrier. It would be interesting to know if the latter is during implementation and the former is after. As nationwide adoption of a fully interoperable EHR progresses, many barriers identified in this review such as standards, and resistance to change could be mitigated. As more data becomes available through the EHR, relationships to outcomes should appear. Appropriate training on EHRs use, may help with the level of complexity among health care providers and their staff.

The EHR can improve health care productivity and efficiency to better serve public health. An abundance of health care information can be managed through databases by using electronic medical records, and this makes data more easily shared between providers and organizations.

## Compliance with ethical standards

**Conflicts of interest** The authors declare that they have no conflict of interest.

**Ethical approval** For this type of review, formal consent is not required. This article does not contain any studies with human participants or animals performed by any of the authors.
